16. Abstract  The objective of this study was to develop a suitable replacement for the downstream “turndown” guardrail anchor system. The “turndown” guardrail anchor system does not meet mandated test requirements under <i>MASH</i> for upstream anchor application terminals; however, it does meet downstream requirements for previous crash testing standards. Due to its low cost, TxDOT has used this anchor system with 27-inch guardrail in downstream applications when it is outside of the clear zone of opposing traffic. With the new federally mandated increase in guardrail height, TxDOT is considering increasing its standard guardrail height to 31 inches. This increase in height increases the risk of a small sedan wedging under the guardrail and snagging on the “turndown” anchor system. The current “turndown” anchor design does not include a releasable connection detail for reverse direction impacts. For this reason, TxDOT has decided to develop a new downstream anchor system rather than test the 31-inch configuration of the “turndown” anchor system.  This anchor system utilized standard parts found in the AASHTO-ARTBA-AGC <i>Guide to Standardized Highway Barrier Hardware</i> when possible. This terminal is nonproprietary to allow for competitive bidding to reduce costs. As this system will be developed for the sole purpose of anchoring the downstream end of guardrail system, the testing matrix will include the optional crash test (3-37) found in <i>MASH</i> for testing terminals in a reverse direction impact condition.

## DISCLAIMER

This research was performed in cooperation with the Texas Department of Transportation (TxDOT) and the Federal Highway Administration (FHWA). The contents of this report reflect the views of the authors, who are responsible for the facts and the accuracy of the data presented herein. The contents do not necessarily reflect the official view or policies of the FHWA or TxDOT. This report does not constitute a standard, specification, or regulation, and its contents are not intended for construction, bidding, or permit purposes. In addition, the above-listed agencies assume no liability for its contents or use thereof. The United States Government and the State of Texas do not endorse products or manufacturers. Trade or manufacturers' names appear herein solely because they are considered essential to the object of this report. The engineer in charge of the project was Roger P. Bligh, P.E. (Texas, #78550).

## TTI PROVING GROUND DISCLAIMER

The full-scale crash test reported herein was performed at Texas Transportation Institute (TTI) Proving Ground. TTI Proving Ground is an International Standards Organization (ISO) 17025 accredited laboratory with American Association for Laboratory Accreditation (A2LA) Mechanical Testing certificate 2821.01. The full-scale crash test was performed according to TTI Proving Ground quality procedures and according to the *MASH* guidelines and standards. The results of the crash testing reported herein apply only to the article being tested.

# CHAPTER 1. INTRODUCTION

## 1.1 INTRODUCTION

This project was set up to provide Texas Department of Transportation (TxDOT) with a mechanism to quickly and effectively evaluate high-priority issues related to roadside safety devices. Roadside safety devices shield motorists from roadside hazards such as non-traversable terrain and fixed objects. To maintain the desired level of safety for the motoring public, these safety devices must be designed to accommodate a variety of site conditions, placement locations, and a changing vehicle fleet. Periodically, there is a need to assess the compliance of existing safety devices with current vehicle testing criteria and develop new devices that address identified needs.

Under this project, roadside safety issues were identified and prioritized for investigation. The selected safety issues were evaluated through crash data analyses, engineering analyses, computer simulation, dynamic impact testing, and full-scale crash testing as appropriate. Factors such as impact performance, maintenance, and cost were considered. Each roadside safety issue is addressed with a separate work plan, and the results are summarized in an individual test report.

One problem prioritized by the TxDOT review panel included the development of a suitable replacement for the downstream “turndown” guardrail anchor system. The “turndown” guardrail anchor system does not meet mandated test requirements under the American Association of State Highway and Transportation Officials (AASHTO) *Manual for Assessing Safety Hardware (MASH)* (1) for upstream anchor application. However, it does meet downstream requirements for previous crash testing standards. Due to its low costs, TxDOT has used this anchor system with 27-inch guardrail in downstream applications when it is outside of the clear zone of opposing traffic. With the new federally mandated increase in guardrail height, TxDOT is considering increasing its standard guardrail height to 31 inches. This increase in height increases the risk of a small sedan wedging under the guardrail and snagging on the “turndown” anchor system. The current “turndown” anchor design does not include a releasable connection detail for reverse direction impacts. For this reason, TxDOT has decided to develop a new downstream anchor system rather than test the 31-inch configuration of the “turndown” anchor system.

The anchor system should utilize standard parts found in the American Association of State Highway and Transportation Officials-American Road and Transportation Builders Association-Association of General Contractors of America (AASHTO-ARTBA-AGC) *Guide to Standardized Highway Barrier Hardware* when possible (2). The terminal should be nonproprietary to allow for competitive bidding to reduce costs. As this system will be developed for the sole purpose of anchoring the downstream end of guardrail system, the testing matrix will include the optional crash test (3-37) found in *MASH* for testing terminals in a reverse direction impact condition.

## 1.2 BACKGROUND

AASHTO published *MASH* in October 2009. *MASH* supersedes *National Cooperative Highway Research Program (NCHRP) Report 350 (3)* as the recommended guidance for the safety performance evaluation of roadside safety features. Changes incorporated into the new guidelines include new design test vehicles, revised test matrices, and revised impact conditions.

The test matrix found in *NCHRP Report 350* and *MASH* for developing guardrail terminals has generally been costly for states to develop nonproprietary designs. The current *MASH* testing matrix includes a total of eight tests, inflating the cost for development of an end terminal to over \$500,000. For this reason, private entities have developed most of the systems that are currently available, which are considered proprietary to protect their extensive investment. This, combined with the increased cost due to the added complexity associated with safely redirecting, absorbing, or gating an impact upstream of the length of need (LON), have increased the cost of terminals.

Terminals developed for end-on impacts are required to have upstream anchorage and downstream anchorage of guardrails when inside the clear zone of opposing travel lanes. This, however, is not the case for downstream anchor systems installed outside of the clear zone of opposing travel lanes. By removing the end-on impact condition, an anchor system cost and complexity can be dramatically reduced. One instance of this is the TxDOT downstream “turndown” anchor system. The TxDOT “turndown” guardrail anchor system does not meet mandated test requirements under *MASH* for upstream anchor application. However, it does meet downstream requirements for previous crash testing standards. Due to its low cost, TxDOT has used this anchor system with 27-inch guardrails in downstream applications when it is outside of the clear zone of opposing traffic.

With the new federally mandated increase in guardrail height, TxDOT is considering increasing its standard guardrail height to 31 inches. This increase in height increases the risk of a small sedan wedging under the guardrail and snagging on the “turndown” anchor system. The current “turndown” anchor design does not include a releasable connection detail for reverse direction impacts. For this reason, TxDOT has decided to develop a new downstream anchor system rather than test the 31-inch configuration of the “turndown” anchor system.

## 1.3 OBJECTIVES/SCOPE OF RESEARCH

The objective of this test was to develop and evaluate the performance of the TxDOT 31-inch W-Beam Downstream Anchor Terminal according to the *MASH* standards for Test Level 3 (TL-3) terminals. The test performed was *MASH* test 3-37, which typically involves a 2270P (5004 lb) pickup truck impacting the critical impact point (CIP) of the terminal in the reverse direction of traffic at a nominal impact speed and angle of 62 mi/h and 25 degrees, respectively. This test will evaluate the ability of the terminal to successfully release when a heavy vehicle impacts it. However, in the test reported here, the 1100C (2425 lb) small car was used to maximize the risk of wedging the vehicle under the raised 31-inch guardrail, increasing the risk of snagging on the anchor post. The anchor system used standard parts found in the AASHTO-

ARTBA-AGC *Guide to Standardized Highway Barrier Hardware* when possible. This terminal is nonproprietary to allow for competitive bidding to reduce costs.

This report gives the details of the TxDOT 31-inch W-Beam Downstream Anchor Terminal, test conditions, description of the test performed, and an assessment of the test results.

## CHAPTER 2. SYSTEM DETAILS

### 2.1 TEST ARTICLE DESIGN AND CONSTRUCTION

The TxDOT 31-inch W-Beam Downstream Anchor Terminal had a total length of 118 ft–9 inches. The upstream end of the installation was anchored using a standard 31-inch ET terminal. The length of need was supported using a standard 72-inch W6×8.5 steel line post with an 8-inch wood blackout. Posts were spaced every 75 inches with the rail splices falling at the mid-span between posts. This system provided a length of need of 87 ft–6 inches.

The test article is a modification of a breakaway cable terminal (BCT). All components of the terminal were standard, off-the-shelf parts from the AASHTO-ARTBA-AGC *Guide to Standardized Highway Barrier Hardware*. The terminal utilizes two 6-inch × 8-inch × 72-inch foundation tubes. In each foundation tube, a 6-inch × 8-inch wooden breakaway post was placed. These foundations were spaced 72 inches from center to center. The two foundation tubes were then linked together at ground level using two C3×5 channel sections. This design was a simplification of the original welded channel section found in the AASHTO-ARTBA-AGC *Guide to Standardized Highway Barrier Hardware*. A 9 ft–4.5 inch anchor rail segment was used to facilitate the attachment to a 31-inch guardrail installation with splices placed at the mid-span. This leads to a terminal length of only 9 ft–4 inches.

The anchor post was not bolted to the rail to prevent the rail from fracturing the anchor post in the event of a reverse direction impact. Instead, a standard “shelf angle bracket” (ARTBA #FPP02) supported the rail in the vertical direction in the event of a redirection impact upstream of the guardrail anchor terminal. A W-beam end section (ARTBA #RWE03a) was used to finish the end of the rail, and a standard breakaway anchor cable (ARTBA #FCA01) was used in conjunction with a guardrail anchor bracket (ARTBA #FPA01) to anchor the system. Figure 2.1 and Appendix A give further system details and installation details, and Figure 2.2 presents photographs of the installation.

### 2.2 MATERIAL SPECIFICATIONS

All rolled steel shapes were fabricated to meet American Society for Testing and Materials (ASTM) A36 specifications, and the foundation tubes, according to ASTM A500 grade B specifications. All other components were manufactured to meet specifications defined in the AASHTO-ARTBA-AGC *Guide to Standardized Highway Barrier Hardware*.

### 2.3 SOIL CONDITIONS

In accordance with Appendix B of *MASH*, soil strength was measured on the day of the crash test (see Appendix C, Figure C1). During construction of the TxDOT 31-inch W-Beam Downstream Anchor Terminal for the full-scale crash test, two W6×16 posts were installed in the

immediate vicinity of the terminal using the same fill materials and installation procedures followed for the terminal and used in the reference tests (see Appendix C, Figure C2).

As determined from the reference tests shown in Appendix C, Figure C2, the minimum static post load required for deflections of 5 inches, 10 inches, and 15 inches, measured at a height of 25 inches, is 3940 lb, 5500 lb, and 6540 lb, respectively (90 percent of static load for the initial reference installation). On the day of the test, April 20, 2011, load on the post at deflections of 5 inches, 10 inches, and 15 inches was 9515 lbf, 9242 lbf, and 8909 lbf, respectively. The strength of the backfill material met minimum requirements.

## CHAPTER 3. TEST REQUIREMENTS AND EVALUATION CRITERIA

### 3.1 CRASH TEST MATRIX

According to *MASH*, up to eight tests are recommended to evaluate W-beam guardrail terminals to test level three (TL-3). Details of these tests are described below.

1. ***MASH* test designation 3-30:** An 1100C (2425 lb) passenger car impacting the terminal end-on at a nominal impact speed and angle of 62 mi/h and 0 degree, respectively, with the quarter point of the vehicle aligned with the centerline of the nose of the terminal. This test is primarily intended to evaluate occupant risk and vehicle trajectory criteria.
2. ***MASH* test designation 3-31:** A 2270P (5000 lb) pickup truck impacting the terminal end-on at a nominal impact speed and angle of 62 mi/h and 0 degree, respectively, with the centerline of the vehicle aligned with the centerline of the nose of the terminal. This test is primarily intended to evaluate occupant risk and vehicle trajectory criteria.
3. ***MASH* test designation 3-32:** An 1100C (2425 lb) passenger car impacting the terminal end on at a nominal impact speed of 62 mi/h and the critical impact angle ranging from 5 to 15 degrees, with the centerline of the vehicle aligned with the centerline of the nose of the terminal. The test is primarily intended to evaluate occupant risk and vehicle trajectory criteria.
4. ***MASH* test designation 3-33:** A 2270P (5000 lb) pickup truck impacting the terminal end-on at a nominal impact speed of 62 mi/h and the critical impact angle ranging from 5 to 15 degrees, with the centerline of the vehicle aligned with the centerline of the nose of the terminal. The test is primarily intended to evaluate occupant risk and vehicle trajectory criteria.
5. ***MASH* test designation 3-34:** An 1100C (2425 lb) passenger car impacting the terminal at a nominal impact speed and angle of 62 mi/h and 15 degrees, respectively, with the corner of the bumper aligned with the critical impact point (CIP) of the length of need (LON) of the terminal. The test is primarily intended to evaluate occupant risk and vehicle trajectory criteria.
6. ***MASH* test designation 3-35:** A 2270P (5000 lb) pickup truck impacting the terminal at a nominal impact speed and angle of 62 mi/h and 25 degrees, respectively, with the corner of the bumper aligned with the beginning of the LON of the terminal. The test is primarily intended to evaluate structural adequacy and vehicle trajectory criteria.
7. ***MASH* test designation 3-37:** A 2270P (5000 lb) pickup truck impacting the terminal at a nominal impact speed and angle of 62 mi/h and 25 degrees,

respectively, midpoint between the nose and the end of the terminal in the reverse direction. This test is intended to evaluate the performance of a terminal for a “reverse” hit.

8. ***MASH* test designation 3-38:** A 1500C (3300 lb) passenger car impacting the terminal end-on at a nominal impact speed and angle of 62 mi/h and 0 degree, respectively, with the centerline of the vehicle aligned with the centerline of the nose of the terminal. This test is intended to evaluate the performance of a staged energy-absorbing terminal when impacted by a mid-size vehicle.

The test reported here corresponds to *MASH* test designation 3-37. However, the vehicle used in the test reported here was the 1100C (2425 lb) small car due to its higher risk of wedging under the breakaway anchor cable in a reverse direction impact event. This, in turn, would lead to a higher risk of snagging on the anchor cable and anchor post, possibly causing elevated occupant risk numbers. The target impact point was 15 ft-7.5 inches upstream of downstream anchor post (37 inches upstream of post 18). This impact location was determined to be the CIP through review of the previous length-of-need test on the 31-inch guardrail with 8-inch blockouts (4).

The crash test and data analysis procedures were in accordance with the guidelines presented in *MASH*. Chapter 4 presents brief descriptions of these procedures.

## **3.2 EVALUATION CRITERIA**

The crash test was evaluated in accordance with the criteria presented in *MASH*. The performance of the TxDOT 31-inch W-Beam Downstream Anchor Terminal is judged on the basis of three factors: structural adequacy, occupant risk, and post-impact vehicle trajectory. Structural adequacy is judged on the ability of the TxDOT 31-inch W-Beam Downstream Anchor Terminal to contain and redirect the vehicle, or bring the vehicle to a controlled stop in a predictable manner. Occupant risk criteria evaluate the potential risk of hazard to occupants in the impacting vehicle, and, to some extent, other traffic, pedestrians, or workers in construction zones, if applicable. Post-impact vehicle trajectory is assessed to determine potential for secondary impact with other vehicles or fixed objects, creating further risk of injury to occupants of the impacting vehicle and/or risk of injury to occupants in other vehicles. The appropriate safety evaluation criteria from table 5-1 of *MASH* were used to evaluate the crash test reported here, and are listed in further detail under the assessment of the crash test.

## **CHAPTER 4. CRASH TEST PROCEDURES**

### **4.1 TEST FACILITY**

The full-scale crash test reported here was performed at Texas Transportation Institute (TTI) Proving Ground. TTI Proving Ground is an International Standards Organization (ISO) 17025 accredited laboratory with American Association for Laboratory Accreditation (A2LA) Mechanical Testing certificate 2821.01. The full-scale crash test was performed according to TTI Proving Ground quality procedures and according to the *MASH* guidelines and standards.

The Texas Transportation Institute Proving Ground is a 2000-acre complex of research and training facilities located 10 miles northwest of the main campus of Texas A&M University. Formerly an Air Force base, the site has large expanses of concrete runways and parking aprons well-suited for experimental research and testing in the areas of vehicle performance and handling, vehicle-roadway interaction, durability and efficacy of highway pavements, and safety evaluation of roadside safety hardware. The site selected for construction and testing of the TxDOT 31-inch W-Beam Downstream Anchor Terminal evaluated under this project was along the edge of an out-of-service apron. The apron is an unreinforced jointed-concrete pavement in 12.5 ft × 15 ft blocks nominally 8–12 inches deep. It is over 50 years old, and its joints have some displacement, but are otherwise flat and level.

### **4.2 VEHICLE TOW AND GUIDANCE PROCEDURES**

The test vehicle was towed into the test installation using a steel cable guidance and reverse tow system. A steel cable for guiding the test vehicle was tensioned along the path, anchored at each end, and threaded through an attachment to the front wheel of the test vehicle. An additional steel cable was connected to the test vehicle, passed around a pulley near the impact point, through a pulley on the tow vehicle, and then anchored to the ground such that the tow vehicle moved away from the test site. A two-to-one speed ratio between the test and tow vehicle existed with this system. Just prior to impact with the installation, the test vehicle was released to be free-wheeling and unrestrained. The vehicle remained free-wheeling, i.e., no steering or braking inputs, until the vehicle cleared the immediate area of the test site, at which time brakes on the vehicle were activated to bring it to a safe and controlled stop.

### **4.3 DATA ACQUISITION SYSTEMS**

#### **4.3.1 Vehicle Instrumentation and Data Processing**

The test vehicle was instrumented with a self-contained, on-board data acquisition system. The signal conditioning and acquisition system is a 16-channel, Tiny Data Acquisition System (TDAS) Pro produced by Diversified Technical Systems, Inc. The accelerometers, that measure the  $x$ ,  $y$ , and  $z$  axis of vehicle acceleration, are strain gauge type with linear millivolt output proportional to acceleration. Angular rate sensors, measuring vehicle roll, pitch, and yaw

rates, are ultra small, solid state units designed for crash test service. The TDAS Pro hardware and software conform to the latest SAE J211, Instrumentation for Impact Test. Each of the 16 channels is capable of providing precision amplification, scaling, and filtering based on transducer specifications and calibrations. During the test, data are recorded from each channel at a rate of 10,000 values per second with a resolution of one part in 65,536. Once the data are recorded, internal batteries back these up inside the unit, should the primary battery cable be severed. Initial contact of the pressure switch on the vehicle bumper provides a time zero mark as well as initiating the recording process. After each test, the data are downloaded from the TDAS Pro unit into a laptop computer at the test site. The Test Risk Assessment Program (TRAP) software then processes the raw data to produce detailed reports of the test results. Each of the TDAS Pro units is returned to the factory annually for complete recalibration. Accelerometers and rate transducers are also calibrated annually with traceability to the National Institute for Standards and Technology.

TRAP uses the data from the TDAS Pro to compute occupant/compartiment impact velocities, time of occupant/compartiment impact after vehicle impact, and the highest 10-millisecond (ms) average ridedown acceleration. TRAP calculates change in vehicle velocity at the end of a given impulse period. In addition, maximum average accelerations over 50-ms intervals in each of the three directions are computed. For reporting purposes, the data from the vehicle-mounted accelerometers are filtered with a 60-Hz digital filter, and acceleration versus time curves for the longitudinal, lateral, and vertical directions are plotted using TRAP.

TRAP uses the data from the yaw, pitch, and roll rate transducers to compute angular displacement in degrees at 0.0001-s intervals and then plots yaw, pitch, and roll versus time. These displacements are in reference to the vehicle-fixed coordinate system with the initial position and orientation of the vehicle-fixed coordinate systems being that of the initial impact.

#### **4.3.2 Anthropomorphic Dummy Instrumentation**

An Alderson Research Laboratories Hybrid II, 50<sup>th</sup> percentile male anthropomorphic dummy, restrained with lap and shoulder belts, was placed in the driver's position of the 1100C vehicle. The dummy was uninstrumented.

#### **4.3.3 Photographic Instrumentation and Data Processing**

Photographic coverage of the test included three high-speed cameras: one overhead with a field of view perpendicular to the ground and directly over the impact point; one placed behind the installation at an angle; and a third placed to have a field of view parallel to and aligned with the installation at the downstream end. A flashbulb activated by pressure-sensitive tape switches was positioned on the impacting vehicle to indicate the instant of contact with the installation and was visible from each camera. The films from these high-speed cameras were analyzed on a computer-linked motion analyzer to observe phenomena occurring during the collision and to obtain time-event, displacement, and angular data. A mini-digital video camera and still cameras recorded and documented conditions of the test vehicle and installation before and after the test.

## CHAPTER 5. CRASH TEST RESULTS

### 5.1 TEST DESIGNATION AND ACTUAL IMPACT CONDITIONS

*MASH* test 3-37 involves a 2270P vehicle weighing 5000 lb  $\pm$  100 lb impacting the terminal in the reverse direction of travel at an impact speed of 62.2 mi/h  $\pm$  2.5 mi/h and an angle of 25 degrees  $\pm$  1.5 degrees. An 1100C impact vehicle was substituted for the 2270P due to its higher risk of wedging under the breakaway anchor cable in a reverse direction impact event. The target impact point was 15 ft-7.5 inches upstream of downstream anchor post (37 inches upstream of post 18). The 2004 Kia Rio used in the test weighed 2420 lb and the actual impact speed and angle were 61.9 mi/h and 25.3 degrees, respectively. The actual impact point was 36 inches upstream of post 18.

### 5.2 TEST VEHICLE

The 2004 Kia Rio, shown in Figures 5.1 and 5.2, was used for the crash test. Test inertia weight of the vehicle was 2420 lb, and its gross static weight was 2585 lb. The height to the lower edge of the vehicle bumper was 8.5 inches, and it was 22.75 inches to the upper edge of the bumper. Table D1 in Appendix D gives additional dimensions and information on the vehicle. The vehicle was directed into the installation using the cable reverse tow and guidance system, and was released to be free-wheeling and unrestrained just prior to impact.

### 5.3 WEATHER CONDITIONS

The test was performed on the morning of April 20, 2011. No rainfall was recorded for the 10 days prior to the test. Weather conditions at the time of testing were: Wind speed: 9 mi/h; Wind direction: 180 degrees with respect to the vehicle (vehicle was traveling in a northwesterly direction); Temperature: 81°F, Relative humidity: 71 percent.

### 5.4 TEST DESCRIPTION

The 2004 Kia Rio, traveling at an impact speed of 61.9 mi/h, impacted the terminal 37 inches upstream of post 18 at an impact angle of 25.3 degrees. At approximately 0.024 s after impact, the left front corner of the vehicle contacted post 18, and at 0.054 s, the vehicle began to redirect. The rail segment at the end of the terminal separated from post 20 at 0.059 s, and post 19 and 20 began to deflect toward the field side at 0.070 s. At 0.095 s, the vehicle contacted post 19, and at 0.097 s, post 19 began to shatter. At 0.160 s, post 20 began to rise upward, and at 0.176 s, the front of the vehicle contacted post 20, which continued to rise upward. The vehicle lost contact with the terminal at 0.217 s, and was traveling at an exit speed and angle of 40.2 mi/h and 18.4 degrees, respectively. Brakes on the vehicle were applied at 0.540 s after impact, and the vehicle came to rest 140 ft downstream of impact and 7.5 ft toward traffic lanes. Figures E1 and D2 in Appendix E show sequential photographs of the test period.

**Figure 5.1. Vehicle/Installation Geometrics for Test No. 420021-1.**

**Figure 5.2. Vehicle before Test No. 420021-1.**

## **5.5 DAMAGE TO TEST INSTALLATION**

Figures 5.3 and 5.4 show the damage to the TxDOT 31-inch W-Beam Downstream Anchor Terminal. The soil was disturbed around post 15, and post 16 was leaning downstream 0.25 inch. Post 17 was leaning toward the field side 1.5 inches and there was a 0.25 inch gap in the soil on the upstream side of the post, and 1.0 inch on the downstream side. Post 18 was leaning 30 degrees downstream and was pushed toward the field side 5.5 inches. Post 19 fractured at ground level and was resting 50 ft toward the field side directly behind its original position. Post 20 fractured at ground level and was resting 82.5 ft downstream of impact and 30 ft toward the field side. The W-beam rail element detached from posts 18 through 20. The end of the guardrail was resting on the ground approximately 16 ft toward the field. Working width was 16 ft. Length of contact of the car with the rail element was 15.6 ft. Maximum dynamic deflection of the W-beam rail element was 16 ft.

## **5.6 VEHICLE DAMAGE**

As shown in Figure 5.5, the vehicle sustained damage to the front and left front quarter. The left strut and tower and left lower ball joint were damaged. The front bumper, hood, radiator and support, left front tire and wheel rim, and left front fender were also damaged. The windshield sustained stress cracks from the left lower corner, and the left side of the floor pan was very slightly damaged. Maximum exterior crush to the vehicle was 14.0 inches in the side plane at the left front corner at bumper height. No occupant compartment deformation occurred. Photographs of the interior of the vehicle are shown in Figure 5.6. Appendix D, Tables D2 and D3 have data on the exterior crush and occupant compartment deformation.

## **5.7 OCCUPANT RISK FACTORS**

Data from the accelerometer, located at the vehicle center of gravity, were digitized for evaluation of occupant risk. In the longitudinal direction, the occupant impact velocity was 21.0 ft/s at 0.140 s, the highest 0.010-s occupant ridedown acceleration was 9.7 Gs from 0.163 s to 0.173 s, and the maximum 0.050-s average acceleration was -7.5 Gs between 0.033 s and 0.083 s. In the lateral direction, the occupant impact velocity was 14.8 ft/s at 0.140 s, the highest 0.010-s occupant ridedown acceleration was 6.6 Gs from 0.140 s to 0.150 s, and the maximum 0.050-s average was 5.6 Gs between 0.030 s and 0.080 s. Theoretical Head Impact Velocity (THIV) was 27.2 km/h or 7.6 m/s at 0.136 s; Post-Impact Head Decelerations (PHD) was 10.2 Gs between 0.163 s and 0.173 s; and Acceleration Severity Index (ASI) was 0.86 between 0.029 s and 0.079 s. Figure 5.7 summarizes these data and other pertinent information from the test. Appendix F, Figures F1 through F7 present data on vehicle angular displacements and accelerations versus time traces. .

Test Agency ..... Texas Transportation Institute (TTI)  
 Test Standard Test No. .... MASH Test 3-37  
 TTI Test No. .... 420021-1  
 Test Date ..... 2011-04-20

#### Test Article

Type ..... Terminal  
 Name ..... TxDOT 31-inch W-Beam Downstream  
 Anchor Terminal  
 Installation Length ..... 118 ft 9 inches  
 Material or Key Elements ..... W-beam guardrail with modified  
 breakaway cable terminal

#### Soil Type and Condition

Standard Soil, Dry

#### Test Vehicle

Type/Designation ..... 1100C  
 Make and Model ..... 2004 Kia Rio  
 Curb ..... 2384 lb  
 Test Inertial ..... 2420 lb  
 Dummy ..... 165 lb  
 Gross Static ..... 2585 lb

#### Impact Conditions

Speed ..... 61.9 mi/h  
 Angle ..... 25.3 degrees  
 Location/Orientation ..... 36 inches upstrm  
 of post 18

#### Exit Conditions

Speed ..... 40.2 mi/h  
 Angle ..... 18.4 degrees

#### Occupant Risk Values

Impact Velocity  
 Longitudinal ..... 21.0 ft/s  
 Lateral ..... 14.8 ft/s  
 Ridedown Accelerations  
 Longitudinal ..... 9.7 G  
 Lateral ..... 6.6 G  
 THIV ..... 27.2 km/h  
 PHD ..... 10.2 G  
 ASI ..... 0.86  
 Max. 0.050-s Average  
 Longitudinal ..... -7.5 G  
 Lateral ..... -5.6 G  
 Vertical ..... -3.7 G

#### Post-Impact Trajectory

Stopping Distance ..... 140 ft downstrm  
 7.5 ft twd traffic

#### Vehicle Stability

Maximum Yaw Angle ..... 31 degrees  
 Maximum Pitch Angle ..... -4 degrees  
 Maximum Roll Angle ..... -11 degrees  
 Vehicle Snagging ..... No  
 Vehicle Pocketing ..... No

 Max. Exterior Deformation ..... 14.0 inches  
 OCDI ..... LF0000000  
 Max. Occupant Compartment  
 Deformation ..... 0

**Figure 5.7. Summary of Results for MASH Test 3-37 on the TxDOT 31-inch W-Beam Downstream Anchor Terminal.**

## CHAPTER 6. SUMMARY AND CONCLUSIONS

### 6.1 ASSESSMENT OF TEST RESULTS

An assessment of the test based on the applicable *MASH* safety evaluation criteria is provided below.

#### 6.1.1 Structural Adequacy

- A. *Test article should contain and redirect the vehicle or bring the vehicle to a controlled stop; the vehicle should not penetrate, underride, or override the installation although controlled lateral deflection of the test article is acceptable.*

Results: The TxDOT 31-inch W-Beam Downstream Anchor Terminal contained and redirected the 1100C vehicle. The vehicle did not penetrate, underride, or override the installation. Maximum dynamic deflection of the W-beam rail element was 16 ft. (PASS)

#### 6.1.2 Occupant Risk

- D. *Detached elements, fragments, or other debris from the test article should not penetrate or show potential for penetrating the occupant compartment, or present an undue hazard to other traffic, pedestrians, or personnel in a work zone.*

*Deformation of, or intrusions into, the occupant compartment should not exceed limits set forth in Section 5.3 and Appendix E of MASH. (roof  $\leq 4.0$  inches; windshield =  $\leq 3.0$  inches; side windows = no shattering by test article structural member; wheel/foot well/toe pan  $\leq 9.0$  inches; forward of A-pillar  $\leq 12.0$  inches; front side door area above seat  $\leq 9.0$  inches; front side door below seat  $\leq 12.0$  inches; floor pan/transmission tunnel area  $\leq 12.0$  inches)*

Results: Post 19 fractured at ground level and was resting 50 ft toward the field side directly behind its original position. Post 20 fractured at ground level and was resting 82.5 ft downstream of impact and 30 ft toward the field side. These fragments did not penetrate, nor to show potential for penetrating the occupant compartment. No deformation or intrusion of the occupant compartment occurred. (PASS)

- F. *The vehicle should remain upright during and after collision. The maximum roll and pitch angles are not to exceed 75 degrees.*

Results: The 1100C vehicle remained upright during and after the collision event. Maximum roll and pitch angles were  $-11$  and  $-4$  degrees, respectively. (PASS)

- H. Occupant impact velocities should satisfy the following:  
Longitudinal and Lateral Occupant Impact Velocity

<u>Preferred</u>	<u>Maximum</u>
30 ft/s	40 ft/s

Results: Longitudinal occupant impact velocity was 21.0 ft/s, and lateral occupant impact velocity was 14.8 ft/s. (PASS)

- I. Occupant ridedown accelerations should satisfy the following:  
Longitudinal and Lateral Occupant Ridedown Accelerations

<u>Preferred</u>	<u>Maximum</u>
15.0 Gs	20.49 Gs

Results: Longitudinal ridedown acceleration was 9.7 G, and lateral ridedown acceleration was 6.6 G. (PASS)

### 6.1.3 Vehicle Trajectory

- N. Vehicle trajectory behind the test article is acceptable.

Result: The 1100C vehicle came to rest 7.5 ft toward the traffic side. (N/A)

## 6.2 CONCLUSIONS

Table 6.1 shows that the TxDOT 31-inch W-Beam Downstream Anchor Terminal performed acceptably for *MASH* test 3-37. The terminal successfully released the anchor cable and the vehicle gated through without snagging on the anchor post in an impact downstream of the length of need of the barrier system. Previous crash testing has shown that this anchor system provides sufficient capacity to redirect a vehicle impact in the LON of a connected guardrail system. The TxDOT 31-inch W-Beam Downstream Anchor Terminal would, therefore, be acceptable to provide anchorage for guardrail systems, provided it is only installed in a downstream configuration outside of the clear zone of opposing traffic lanes.

**Table 6.1. Performance Evaluation Summary for MASH Test 3-37 on the TxDOT 31-inch W-Beam Downstream Anchor Terminal.**

Test Agency: Texas Transportation Institute

Test No.: 420021-1

Test Date: 2011-04-20

<b>MASH Test 3-37 Evaluation Criteria</b>	<b>Test Results</b>	<b>Assessment</b>
<b>Structural Adequacy</b> <b>A.</b> <i>Test article should contain and redirect the vehicle or bring the vehicle to a controlled stop; the vehicle should not penetrate, underride, or override the installation although controlled lateral deflection of the test article is acceptable.</i>	The TxDOT 31-inch W-Beam Downstream Anchor Terminal contained and redirected the 1100C vehicle. The vehicle did not penetrate, underride, or override the installation. Maximum dynamic deflection of the W-beam rail element was 16 ft.	Pass
<b>Occupant Risk</b> <b>D.</b> <i>Detached elements, fragments, or other debris from the test article should not penetrate or show potential for penetrating the occupant compartment, or present an undue hazard to other traffic, pedestrians, or personnel in a work zone.</i>	Posts 19 and 20 fractured at ground level, with 19 resting 50 ft toward the field side directly behind its original position, and 20 resting 82.5 ft downstream of impact and 30 ft toward the field side. These fragments did not penetrate, nor showed potential for penetrating, the occupant compartment.	Pass
<i>Deformations of, or intrusions into, the occupant compartment should not exceed limits set forth in Section 5.3 and Appendix E of MASH.</i>	No deformation or intrusion of the occupant compartment occurred.	Pass
<b>F.</b> <i>The vehicle should remain upright during and after collision. The maximum roll and pitch angles are not to exceed 75 degrees.</i>	The 1100C vehicle remained upright during and after the collision event. Maximum roll and pitch angles were -11 and -4 degrees, respectively.	Pass
<b>H.</b> <i>Longitudinal and lateral occupant impact velocities should fall below the preferred value of 30 ft/s, or at least below the maximum allowable value of 40 ft/s.</i>	Longitudinal occupant impact velocity was 21.0 ft/s, and lateral occupant impact velocity was 14.8 ft/s.	Pass
<b>I.</b> <i>Longitudinal and lateral occupant ridedown accelerations should fall below the preferred value of 15.0 Gs, or at least below the maximum allowable value of 20.49 Gs.</i>	Longitudinal ridedown acceleration was 9.7 G, and lateral ridedown acceleration was 6.6 G.	Pass
<b>Vehicle Trajectory</b> <b>N.</b> <i>Vehicle trajectory behind the test article is acceptable.</i>	The 1100C vehicle came to rest 7.5 ft toward the traffic side.	N/A

## CHAPTER 7. IMPLEMENTATION STATEMENT

Installation details for the TxDOT 31-inch W-Beam Downstream Anchor Terminal are included in Appendix A and the AASHTO-ARTBA-AGC *Guide to Standardized Highway Barrier Hardware*. The Design Division should review these details. If the Division chooses to add this terminal to its current list of hardware standards, then they should develop a standard detail sheet that districts could use across the state as a nonproprietary alternative method for anchoring downstream ends of guardrails outside the clear zone of opposing traffic lanes.

# VEHICLE CRUSH MEASUREMENT SHEET<sup>1</sup>

Complete When Applicable	
End Damage	Side Damage
Undeformed end width _____	Bowing: B1 _____ X1 _____
Corner shift: A1 _____	B2 _____ X2 _____
A2 _____	
End shift at frame (CDC)	Bowing constant
(check one)	$\frac{X1 + X2}{2} = \underline{\hspace{2cm}}$
< 4 inches _____	
≥ 4 inches _____	

Note: Measure C<sub>1</sub> to C<sub>6</sub> from Driver to Passenger side in Front or Rear impacts—Rear to Front in Side Impacts.

[illegible]

<sup>1</sup>Table taken from the National Accident Sampling System (NASS).

\*Identify the plane at which the C-measurements are taken (e.g., at bumper, above bumper, at sill, above sill, at beltline, etc.) or label adjustments (e.g., free space).

Free space value is defined as the distance between the baseline and the original body contour taken at the individual C locations. This may include the following: bumper lead, bumper taper, side protrusion, side taper, etc. Record the value for each C-measurement and maximum crush.

\*\*Measure and document on the vehicle diagram the beginning or end of the direct damage width and field L (e.g., side damage with respect to undamaged axle).

\*\*\*Measure and document on the vehicle diagram the location of the maximum crush.

Note: Use as many lines/columns as necessary to describe each damage profile.

**Table D3. Occupant Compartment Measurements for Test No. 420021-1.**
